Questions

Fix an uncountable Polish space  $X$  (e.g.,  $\mathbb{R}$ ,  $[0, 1]$ ,  $\omega^\omega$ ,  $[\omega]^\omega \dots$ ).  
The Borel ( $\Delta_1^1$ ) subsets of  $X$  is the  $\sigma$ -algebra generated by the open ( $\Sigma_1^0$ ) subsets of  $X$ .

## The projective hierarchy

$\Sigma_1^1$  = analytic sets  
(projections of  $\Pi_1^0$  subsets of  
 $X \times \omega^\omega$ )

$\Sigma_{n+1}^1$  = projections of  $\Pi_n^1$  sets

$\Pi_1^1$  = coanalytic sets  
(complements of  $\Sigma_1^1$  sets)  
 $\Pi_{n+1}^1$  = complements of  $\Sigma_{n+1}^1$  sets

$$\Delta_n^1 = \Sigma_n^1 \cap \Pi_n^1$$

## Definition

A mad family  $\mathcal{A} \in V$  is  $\mathbb{P}$ -indestructible for some forcing notion  $\mathbb{P}$  if  $\mathcal{A}$  remains maximal in any  $\mathbb{P}$ -generic extension over  $V$ .

General strategy:

- Construct a  $\mathbb{P}$ -indestructible mad family in  $L$  in a  $\Sigma_2^1$ -way, where  $\mathbb{P}$  is some forcing adding reals.
- In  $L^\mathbb{P}$ ,  $\mathcal{A}$  is a  $\Sigma_2^1$  mad family, so apply Törnquist's theorem.

## Corollary

- *It is consistent with  $\mathfrak{a} < \mathfrak{c}$  that there exists a coanalytic witness of size  $\mathfrak{a} = \aleph_1$ .*
- *(Brendle, Khomskii [BK13]) It is consistent that  $\aleph_1 < \mathfrak{a} = \mathfrak{c} = \kappa$  regular cardinal, and there exists a coanalytic mad family.*

What we do:

- Survey the literature for implications of the form  $\Sigma_2^1 \Rightarrow \Pi_1^1$ .
  - Maximal independent families, towers, maximal eventually different families of functions, maximal orthogonal families, ultrafilter bases.
- Extract a general framework; present the theorems in a uniform fashion.
  - Essential use of  $\Pi_1^1$ -uniformization, Spector-Gandy theorem.
- Apply the framework to produce a new such theorem: Hausdorff gaps in  $(\mathcal{P}(\omega), \subseteq^*)$ .

See also [Mil24].

The framework is potent: has been applied to several other combinatorial structures (M., Schembecker, 2025 [MS25]).

## Definition

A *pre-gap* is a pair  $(A, B)$  where  $A, B \subseteq [\omega]^\omega$  are wellordered by the relation  $\subseteq^*$ , and for all  $a \in A$  and  $b \in B$ ,  $a \cap b$  is finite.<sup>1</sup>. A pre-gap  $(A, B)$  is a *gap* if there does not exist  $c \in [\omega]^\omega$  such that for all  $a \in A$  and  $b \in B$ ,  $a \cap c$  is finite and  $c \subseteq b$ . (Such a  $c$  *separates*  $A, B$ ).

- Found in work of Hausdorff, Du Bois-Reymond, Hadamard.

## Theorem (Todorcevic, 1996; [Tod96])

Suppose  $(A, B)$  is a pre-gap and  $A$  is analytic. Then  $(A, B)$  can be separated.

---

<sup>1</sup>We define  $x \subseteq^* y$  if and only if  $x \setminus y$  is finite

## Definition

A *Hausdorff gap* is a pre-gap  $(A, B)$ , where  $A = \{a_\alpha \mid \alpha < \omega_1\}$ ,  $B = \{b_\alpha \mid \alpha < \omega_1\}$ , satisfying:

$$\forall \alpha < \omega_1 \forall k < \omega [\{\gamma < \alpha \mid a_\alpha \cap b_\gamma \subseteq k\}] \text{ is finite.}$$

$(A, B)$  is a Hausdorff gap  $\Rightarrow (A, B)$  is a gap.

## Theorem (M., 2024)

If there exists a Hausdorff gap  $(A, B)$  such that both  $A, B$  are  $\Sigma_2^1$ -definable, then there exists a Hausdorff gap  $(A', B')$  such that  $A', B'$  are  $\Pi_1^1$ -definable.

## Corollary

It is consistent with  $\mathfrak{c} > \aleph_1$  that there exists a Hausdorff gap  $(A, B)$ , and  $(A, B)$  are coanalytic.

## Theorem (Fischer, M., 2025)

*It is consistent with  $\mathfrak{a} = \aleph_1 < \mathfrak{s} = \mathfrak{c} = \aleph_2$  that there exists:*

- *A  $\Delta^1_3$  wellorder of the reals;*
- *A coanalytic tight mad family of size  $\aleph_1$ ;*
- *A  $\Pi^1_2$  tight mad family of size  $\aleph_2$ .*

Fixing a  $\Pi^1_1$  tight mad family  $\mathcal{A}$  in  $L$ , there are three tasks:

- 1 Increase the size of  $\mathfrak{s}$ ;
- 2 Add a  $\Delta^1_3$  wellorder of the reals;
- 3 Add a  $\Pi^1_2$  tight mad family of size  $\mathfrak{c}$ .

Crucially, we ensure this can be done without destroying the maximality of  $\mathcal{A}$ , so cannot add dominating reals.

## Definition

- For an almost disjoint family  $\mathcal{A}$ , the *ideal generated by  $\mathcal{A}$*  is the set

$$\mathcal{I}(\mathcal{A}) := \{b \in [\omega]^\omega \mid b \subseteq^* \bigcup F \text{ for some finite } F \subseteq \mathcal{A}\}.$$

- An almost disjoint family  $\mathcal{A}$  is *tight* if for all countable  $\mathcal{B} \subseteq \mathcal{I}(\mathcal{A})^+ = [\omega]^\omega \setminus \mathcal{I}(\mathcal{A})$ , there exists a single  $a \in \mathcal{A}$  such that  $a \cap b$  is infinite for each  $b \in \mathcal{B}$ .

$\mathcal{A}$  is tight  $\Rightarrow$   $\mathcal{A}$  is maximal.

- Exist under CH and  $\mathfrak{b} = \mathfrak{c}$ . Their existence under ZFC is a long standing open problem.
- Introduced by Malykhin [Mal89]; are Cohen-indestructible [Kur01].

## Task 1

Increase  $\mathfrak{s}$ , but do not increase  $\mathfrak{a}$ .

- Mathias forcing: increases  $\mathfrak{s}$  by adding an unsplit real, but also increases  $\mathfrak{b}$ , since it adds a dominating real.
- Shelah's creature forcing  $\mathbb{Q}$  of [She84] increases  $\mathfrak{s}$ , but is *almost  $\omega^\omega$ -bounding*, meaning  $\mathbb{Q}$  (and its iterations) keep  $\mathfrak{b}$  small.
- almost  $\omega^\omega$ -bounding  $\not\Rightarrow$  preserves mad families.
- Original proof of the consistency of  $\mathfrak{b} = \mathfrak{a} < \mathfrak{s}$  was by directly constructing a mad family in the ground model.
- Alan Dow [Dow95] uses a similar approach to show  $\mathfrak{a} = \aleph_1$  in the Miller model.

## Proposition (Fischer, M., 2025)

Let  $\mathbb{Q}$  be Shelah's creature forcing [She84], let  $\mathcal{A} \in V$  be a tight mad family. Then  $\mathbb{Q}$  strongly preserves the tightness of  $\mathcal{A}$ .

This reveals that  $\mathbb{Q}$  has a stronger combinatorial property than almost  $\omega^\omega$ -bounding, and it follows:

## Theorem (Shelah, [She84])

Assume CH, and let  $\mathbb{P}$  be an  $\omega_2$ -length countable support iteration of  $\mathbb{Q}$ , and let  $G$  be  $\mathbb{P}$ -generic over  $V$ . Then  $V[G] \models \aleph_1 = \mathfrak{a} < \mathfrak{s} = \aleph_2$ .

Therefore, also in this model  $\mathfrak{b} < \mathfrak{s}$ .

## Task 2

Add a  $\Delta^1_3$  wellordering of the reals, while preserving a tight mad family in the ground model.

The existence of definable wellorders is a central question in set theory. Projective wellorderings of the reals indicate to what extent regularity properties hold for the projective classes.

- $V = L \Rightarrow$  there exists a  $\Delta^1_2$  wellorder of the reals.
- (Harrington, 1977) A  $\Delta^1_3$  wellorder of the reals is consistent with  $\mathfrak{c}$  arbitrarily large, and Martin's Axiom.
- (Caicedo, Friedman, 2011 [CF11]) Under the Bounded Proper Forcing Axiom and an anti-large cardinal hypothesis, there exists a  $\Delta^1_3$  wellorder of the reals.

## Theorem (Fischer, Friedman, 2010 [FF10])

*Each of the following cardinal inequalities is consistent with  $\mathfrak{c} = \aleph_2$  and the existence of a  $\Delta_3^1$  wellordering of the reals:*  
 $\mathfrak{d} < \mathfrak{c}$ ,  $\mathfrak{b} < \mathfrak{g}$ , and  $\mathfrak{b} < \mathfrak{a} = \mathfrak{s}$ .

- Countable support iteration of  $S$ -proper forcings, where  $S \in L$  is a fixed stationary subset of  $\omega_1$ .
- Generic reals originate from *Sacks coding*: this gives a way of coding with reals via an  $\omega^\omega$ -bounding forcing.
- Coding apparatus: club shooting patterns through an  $\omega_2$ -length sequence of stationary costationary sets from the ground model; David's trick [Dav82].
- “Flexible”: any proper forcing notion of size at most  $\aleph_1$  may be woven in.

Lemma (Bergfalk, Fischer, Switzer, 2022; [BFB22])

*The Sacks coding forcing strongly preserves the tightness of ground model coanalytic tight mad families  $\mathcal{A}$  such that ZFC proves  $\mathcal{A} \subseteq L$ .*

By weaving in the creature forcing to the Fischer-Friedman construction:

Theorem (Fischer, M., 2025)

*It is consistent that there is a  $\Delta_3^1$  wellorder of the reals,  $\aleph_1 = \mathfrak{a} < \mathfrak{s} = \mathfrak{c} = \aleph_2$ , and there is a coanalytic mad family of size  $\aleph_1$ .*

## Task 3

Add a  $\Pi_2^1$  mad family of size  $\mathfrak{c} = \aleph_2$ , while preserving a tight mad family in the ground model.

## Theorem (Friedman, Zdomskyy (2010) [FZ10])

*It is consistent with  $\mathfrak{b} = \mathfrak{c} = \aleph_2$  that there exists a  $\Pi_2^1$  tight mad family.*

- Countable support iteration of  $S$ -proper forcings.
- Appropriate bookkeeping to take care of all  $\mathcal{B} \in [\mathcal{I}(\mathcal{A}_\alpha)^+]^\omega$ , where  $\mathcal{A}_\alpha$  is the family constructed up to stage  $\alpha$ .
- Generic reals arise from *almost-disjoint coding*, a technique of Solovay and Jensen [SJ70], crucial to Harrington's work.
- [FZ10] also adds  $\omega_2$ -many Hechler reals to ensure  $\mathfrak{a} = \mathfrak{c}$ .

## Theorem (Raghavan, [Rag09])

*If  $\mathcal{A}$  is a tight mad family, then  $\mathcal{A}$  does not contain a perfect set.*

## Theorem (Mansfield, Solovay, 1950)

*Suppose  $A$  is a  $\Sigma_2^1$  set of reals such that there exists  $a \in A$  with  $a \notin L$ . Then  $A$  contains a perfect set of nonconstructible reals.*

Hence, the minimal complexity of a projective tight mad family of size  $\geq \aleph_2$  is  $\Pi_2^1$ .

## Proposition

*Let  $\mathbb{K}$  be the Friedman-Zdomskyy forcing for adding a  $\Pi_2^1$  tight mad family of size  $\mathfrak{c}$ . Then  $\mathbb{K}$  strongly preserves the tightness of ground model tight mad families.*

Thus,  $\mathbb{K}$  above does not add dominating reals.

## Theorem (Fischer, M., 2025)

*It is consistent with  $\aleph_1 = \mathfrak{a} < \mathfrak{c} = \aleph_2$  that there exists a coanalytic tight mad family of size  $\aleph_1$  and a  $\Pi_2^1$  tight mad family of size  $\aleph_2$ .*

## Theorem (Fischer, M., 2025, [FM25])

*It is consistent with  $\mathfrak{a} = \aleph_1 < \mathfrak{s} = \mathfrak{c} = \aleph_2$  that there exists:*

- *A  $\Delta_3^1$  wellorder of the reals;*
- *A coanalytic tight mad family of size  $\aleph_1$ ;*
- *A  $\Pi_2^1$  tight mad family of size  $\aleph_2$ .*

## Proof.

Beginning in a model of  $V = L$ , use the template for adding a  $\Delta_3^1$  wellorder, weaving in either:

- 1 Shelah's forcing  $\mathbb{Q}$ ;
- 2 The Friedman-Zdomskyy forcing  $\mathbb{K}$ .

$(1) \Rightarrow \mathfrak{a} = \aleph_1 < \mathfrak{s} = \aleph_2$

$(2) \Rightarrow$  there exists  $\Pi_2^1$  tight mad family of size  $\mathfrak{c}$

## Remark

Some combinatorial families can be analytic, even Borel. This is the case for maximal eventually different families and maximal cofinitary groups ([HS24], [HS25]). Such Borel witnesses are always of size  $\mathfrak{c}$ .

## Theorem

- (Fischer, Schrittesser; [FS21]) *It is consistent with  $\mathfrak{a}_e = \aleph_1 < \mathfrak{c}$  that there exists a coanalytic maximal eventually different family of size  $\aleph_1$*
- (Fischer, Schrittesser, Törnquist; [FST17]) *It is consistent with  $\mathfrak{a}_g = \aleph_1 < \mathfrak{c}$  that there exists a coanalytic maximal cofinitary group of size  $\aleph_1$ .*

## Open questions:

- 1 Can the proofs of the form “if there exists a  $\Sigma_2^1$  family of type  $P$  then there exists a  $\Pi_1^1$  family of type  $P$ ” be lifted to the levels  $\Sigma_{n+1}^1$  and  $\Pi_n^1$ ,  $n \geq 2$ ?
  - Joint work with Fischer, Khomskii, Li.
- 2 Can we have a model with  $\text{spec}(\alpha) > 2$  and for every  $\kappa \in \text{spec}(\alpha)$  there exists a mad family of size  $\kappa$  with an optimal projective definition?
  - Not known how to obtain the above while also demanding  $\aleph_1 \in \text{spec}(\alpha)$ .
